

SWING1_PRO

TradingView User Guide

Setup • reading signals • settings • alerts • backtesting

This guide covers two Pine v6 files for the AAPL 1-minute chart: the **indicator** (**Swing1m_PRO.pine**) that plots BUY / SELL / exit signals live, and the **strategy** (**Swing1m_PRO_strategy.pine**) that runs the same logic through TradingView's Strategy Tester so you can measure win-rate and P&L. Everything below is the same in the desktop app and the website.

1. What each file is for

File	What it does	When to use it
Swing1m_PRO.pine	The indicator. Draws live BUY / SELL / exit markers, the trend line and the fast EMA on your chart. Can fire alerts.	Day-to-day trading & alerts.
Swing1m_PRO_strategy.pine	The strategy. Same signals, but it places simulated orders so the Strategy Tester reports net P&L, win-rate, drawdown, etc.	Backtesting / proving the edge.

Tip: Run them one at a time. Add the indicator for trading; switch to the strategy when you want to backtest. You can keep both saved in your Pine Editor and add whichever you need.

2. Add the indicator to your chart

- 1 Open TradingView and load **AAPL**. Set the timeframe to **1 minute** (type **1** and Enter, or pick 1m in the timeframe menu, top-left).
- 2 Open the **Pine Editor** — the tab along the bottom of the screen. If you don't see it, use the top menu: **View > Pine Editor** (or the bottom toolbar).
- 3 In the editor, select everything in the default template (Ctrl/Cmd-A) and delete it. Open **Swing1m_PRO.pine**, copy ALL of it, and paste it in.
- 4 Click **Save** (top-right of the editor), give it a name like "Swing1m PRO".
- 5 Click **Add to chart** (next to Save). The signals and trend line appear as an overlay, with a status line reading **SWING1_PRO** in the top-left of the chart.

If nothing appears: Make sure the whole file was pasted (it starts with a license comment and `//@version=6`) and that you're on a liquid, open market — the volume filter suppresses signals in dead tape. See Troubleshooting (section 8).

3. Reading the chart

Once it's on the chart, here is what every mark means:

Mark on chart	Meaning
Green BUY label (below a bar)	Long entry signal — the system wants to be long here.
Red SELL label (above a bar)	Short entry signal — the system wants to be short here.
Orange X 'exit' mark	Close the current trade (a stop/target or a momentum-flip exit).
Thick trend line	Teal = up-regime (longs favoured) · Red = down-regime (shorts favoured) · Gray = flat = stand aside.
Thin blue line	The fast pullback EMA — used to time pullback and reversal entries/exits.

How a trade reads: A BUY prints > you're long > later an orange 'exit' (or an opposite SELL) prints > you're flat (or reversed). BUY and SELL strictly alternate unless you turn on re-entries.

4. Configure the settings

Hover the indicator's name on the chart and click the **gear icon** (Settings) > **Inputs** tab. The inputs are grouped. The defaults are already tuned for AAPL 1m, so you can start there and change *one thing at a time*. The groups that matter most:

- **Trend filter** — 'Auto-scale HTF' sets the trend timeframe to 15m on a 1m chart. 'Min trend slope' decides how steep a trend must be before it trades (higher = stricter, fewer signals).
- **Reversals** — this is what catches counter-trend up-moves. 'RSI must be rising and above' (default 40) controls how early reversals fire: **lower = earlier & more**, higher = later & fewer.
- **Quality filters** — 'Cooldown' spaces out signals (higher = fewer), plus candle-agreement and anti-chase guards.
- **Entries & exits** — toggle re-entries, pullback entries, and which exits are active (MACD flip, trend re-cross, RSI, ATR stop/target).
- **ATR stop / target** — sets the stop distance (ATR x) and reward:risk used by the exit logic.

Quick tuning — change the input on the right for the effect on the left:

You want...	Change this
More signals	Lower 'Min trend slope'; lower the Reversal RSI floor; lower Cooldown; lower Volume mult.
Fewer / cleaner signals	Raise 'Min trend slope'; raise Cooldown; raise Volume mult; turn off Reversals or Pullback.
Catch bottoms earlier	Lower the Reversal 'RSI rising above' floor (e.g. 40 > 35).
Tighter / looser exits	Adjust ATR stop x and reward:risk; toggle 'Exit when MACD flips' / '...RSI through 50'.

5. Set up alerts

- 1 Right-click the chart > **Add alert**, or click the **Alerts** (clock) panel on the right > **Create Alert**.
- 2 Set **Condition** to **SWING1_PRO**. A second dropdown appears — choose the event you want: **Swing Buy**, **Swing Sell**, **Exit Long**, **Exit Short**, or **Any signal**.
- 3 Set the trigger to **Once Per Bar Close**. This matches the script's no-repaint behaviour — the signal is final and won't disappear.
- 4 Pick how you're notified (app push, popup, email, or webhook for automation), name it, and click **Create**.

Important: Use **Once Per Bar Close**, not 'Once Per Bar'. The script confirms signals on the close; an intrabar trigger can fire on a candle that later un-paints.

6. Backtest with the strategy version

- 1 In the Pine Editor, open a new tab, paste **Swing1m_PRO_strategy.pine**, **Save**, then **Add to chart**.
- 2 The **Strategy Tester** panel opens at the bottom (or click its tab next to Pine Editor).
- 3 Open the **Properties / Inputs** of the strategy (gear icon) and — this is the step everyone skips — set realistic **Commission** and **Slippage** for your broker. Also check order size and initial capital.
- 4 Read the three tabs: **Overview** (equity curve), **Performance Summary** (the stats), and **List of Trades** (every entry/exit).
- 5 Re-run across **several date ranges**, not just the last few days, before you trust anything.

What the key numbers mean:

Metric	What it tells you	Rough read
Net Profit	Total P&L after costs.	Must be positive AFTER commission + slippage.
Profit Factor	Gross win / gross loss.	>1.3–1.5 = promising; <1.0 = losing.
Percent Profitable	Win rate.	Low win-rate is OK if winners > losers (reversals).
Max Drawdown	Worst peak-to-trough drop.	Can you actually stomach it live?
Total Trades	Sample size.	Want ~100+ for the stats to mean anything.

The cost trap: A 1-minute strategy that looks great at zero cost very often turns into a net loser after 1–2 ticks of slippage and commission. If you set nothing else, set your costs.

Intraday flatten: The strategy closes any open position at 15:55–16:00 by default so a 1m scalp test isn't distorted by overnight gaps. Turn 'Flatten at session close' off if you want it to match the indicator exactly.

7. Troubleshooting

Symptom	Likely cause & fix
No signals at all	Market thin/closed (volume filter), or trend filter too strict. Confirm you're on AAPL 1m during market hours; lower 'Min trend slope'; make sure Reversals is on.
Only SELLS (or only BUYS)	Price stuck on one side of a slow trend line. Reversals (on by default) fix this; confirm the 'Reversals' group is enabled.
Buys fire late / miss the move	Raise how early reversals trigger: lower the Reversal RSI floor (40 > 35) and/or lower Cooldown.
Too many signals / chop	Raise Cooldown and 'Min trend slope', raise Volume mult, or turn off Pullback/Reversals.
Script won't compile	You didn't paste the whole file. It must start with <code>//@version=6</code> . Re-copy all of it.

8. Before you trade real money

- This is a confluence **filter**, not a crystal ball. No indicator predicts price.
- **Paper-trade or sim first.** Watch it live for a few sessions before risking capital.
- On 1m, **costs and slippage dominate** — bake them into every backtest.
- One symbol and one period invites curve-fitting. Validate on other windows and stay skeptical.
- **Not financial advice.** You are responsible for your own trades and risk.
